Viral inhibitors

FIELD OF THE INVENTION

The present invention relates to a series of novel imidazo[4,5-c]pyridine derivatives, processes for their preparation, their use to treat or prevent viral infections and their use to manufacture a medicine to treat or prevent viral infections, preferably infections with viruses belonging to the family of the Flaviviridae and more preferably infections with hepatitis-C-virus (HCV). The present invention also relates to the use of novel imidazo[4,5-c]pyridine derivatives to treat viral infections and their use to manufacture a medicine to treat viral infections, preferably infections with viruses belonging to the family of the Picornaviridae and more preferably infections with Coxsackie viruses.

BACKGROUND OF THE INVENTION

The family of the Flaviviridae consists of 3 genera, the pestiviruses, the flaviviruses and the hepaciviruses and also contains the hepatitis G virus (HGV/GBV-C) that has not yet been assigned to a genus. Pestiviruses such as the Classical Swine Fever Virus (CSFV), the Bovine Viral Diarrhea Virus (BVDV) and the Border Disease Virus (BDV) cause infections of domestic livestock (respectively pigs, cattle and sheep) and are responsible for significant economic losses worldwide. BVDV, the prototypic representative of the pestivirus genus is ubiquitous and causes a range of clinical manifestations, including abortion, teratogenesis, respiratory problems, chronic wasting disease, immune system dysfunction, and predisposition to secondary viral and bacterial infections and may also cause acute fatal disease. Fetuses of cattle can be infected persistently with BVDV, these animals remain viremic throughout life and serve as a continuous sources for virus spread in herds.

Vaccines are used in some countries with varying degrees of success to control pestivirus disease. In other countries, animal culling and slaughter are used to contain pestivirus disease outbreaks (Leyssen P, et al., Clin Microbiol Rev. 2000 Jan;13(1):67-82).

The World Health Organization estimates that world-wide 170 million people are chronically infected with HCV (Leyssen P, et al., Clin Microbiol Rev. 2000 Jan;13(1):67-82). These chronic carriers are at risk of developing cirrhosis and/or liver cancer. The only treatment

option available today is the use of (pegylated) interferon α-2 together with ribavirin. However, the response rate to this treatment is only partial and often transient and treatment is associated with serious adverse effects. The development of new and specific anti-HCV treatments is a high priority. The study of specific inhibitors of HCV replication has been hampered by the fact that it is not possible to propagate HCV (efficiently) in cell culture. Since HCV and pestiviruses belong to the same virus family and share many similarities (organisation of the genome, analogous gene products and replication cycle), pestiviruses have been adopted as a model and surrogate for HCV.

One compound VP32947 or (3-[((2-dipropylamino)ethyl)thio]-5H-1,2,4-triazino[5,6-b]indole has been reported to selectively inhibit the replication of BVDV and other pestiviruses (Baginski SG et al., Proc Natl Acad Sci U S A. 2000 Jul 5;97(14):7981-6). There is no treatment strategy available for controlling infections caused by pestiviruses.

Coxsackie viruses belong to the group of the enteroviruses, family of the Picornaviridae. They cause a heterogeneous group of infections including herpangina, aseptic meningitis, a common-cold-like syndrome, a non-paralytic poliomyelitis-like syndrome, epidemic pleurodynia (an acute, febrile, infectious disease generally occurring in epidemics), hand-foot-mouth syndrome, pediatric and adult pancreatitis and serious myocarditis.

Currently only pleconaril (3-13,5-dimethyl-4-[[3-methyl-5-isoxazolyl)propyl]phenyl]-5-(trifluoromethyl-1,2,4-oxadiazole) and enviroxime [2-amino-1-(isopropylsulfonyl)-6-benzimidazole phenyl ketone oxime] have been studied clinically for the treatment of infections with enteroviruses. Pleconaril is a so called "capsid function-inhibitor"; enviroxime prevents the formation of the RNA replicative intermediate. Enviroxime resulted in only modest clinical and virological benefit in some studies (Phillpotts RJ, Wallace J, Tyrrell DA, Tagart VB. Antimicrob Agents Chemother. 1983 May;23(5):671-5.) and no benefits in others (Miller FD, et al., Chemother. 1985 Jan;27(1):102-6.). Clinical response with pleconaril has been observed in some studies (Rotbart HA, Webster AD. Clin Infect Dis. 2001 Jan 15;32(2):228-35., Rotbart HA. Antiviral Res. 2002 Feb;53(2):83-98), but the compound has not been approved by the Food and Drug Administration (hearing of March 18th, 2002). The inhibitors of Coxsackievirus replication presented here may be used for the treatment of infections with Picornaviridae.

In view of their important pharmacological value, there is a need for drugs having selective activity against viruses belonging to the family of Flaviviridae to which also belongs the hepatitis C virus, and viruses belonging to the family of Picornavidae.

It is the object of the present invention is to provide a novel class of compounds that are active viral inhibitors. One embodiment of present invention are inhibitors of Flaviviridae, preferably inhibitors of the pestivirus replication specifically inhibiting the replication of BVDV; closely related to hepatitis C virus (HCV) and used as a surrogate virus in drug development for HCV infection (Zitzmann N.et al., Proc. Natl. Acad. Sci. USA, 96, 11878-11882 and Bukhtiyarova,-M et al., Antivir-Chem-Chemother. 2001 Nov; 12(6): 367-73). Another embodiment of present invention is a novel class of compounds that can be used for the treatment of infections with Picornaviridae and preferably are active inhibitors of Coxsackievirus replication.

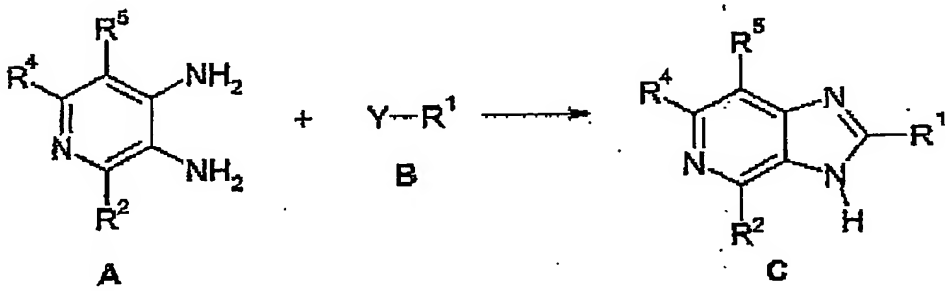
DESCRIPTION OF THE INVENTION

GENERAL METHODS

CHEMISTRY

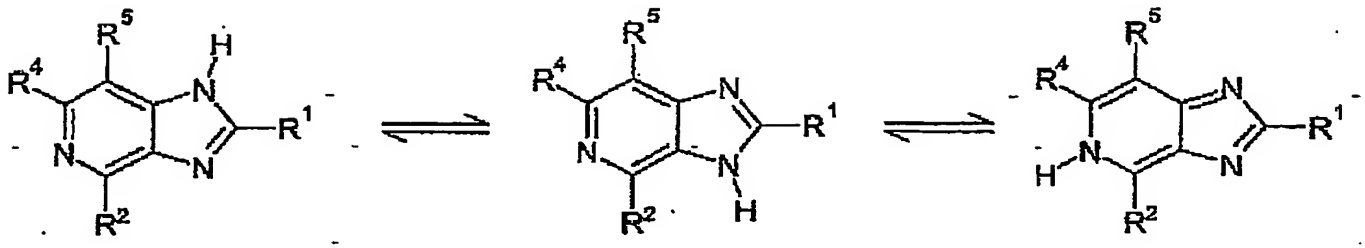
The compounds according to the invention are conveniently prepared in two general steps. First, a (substituted) 3,4-diaminopyridine (A) is reacted with B to give imidazo[4,5-c]pyridines C (scheme 1). If Y is COOH, then the cyclization is carried out under acidic catalysis (preferably in polyphosphoric acid at a temperature between 90 and 200 °C); other methods include reaction in 4N hydrochloric acid at reflux temperature or neat at a temperature between 90 and 180 °C (for aliphatic carboxylic acids). In the case of acid-sensitive groups like alkoxy or thiophene, the reaction can be carried out in phosphorus oxychloride at a temperature between 70 and 120 °C. Alternatively, reaction with aldehydes (Y = CHO) or their bisulfite adducts under oxidative conditions (nitrobenzene, DDQ, copper(II)acetate, O_2, sulfur etc.) gives imidazo[4,5-c]pyridines C. Other methods are the reaction of (substituted) 3,4-diaminopyridines (A) with orthoesters ($Y = C(OR)_3$), anhydrides ($Y = OCOOR$) or acid halogenides ($Y = COX$), etc.

Scheme 1:



The imidazo[4,5-c]pyridines C can be formulated in three tautomeric forms (1*H*, 3*H* or 5*H*), as shown in scheme 2.

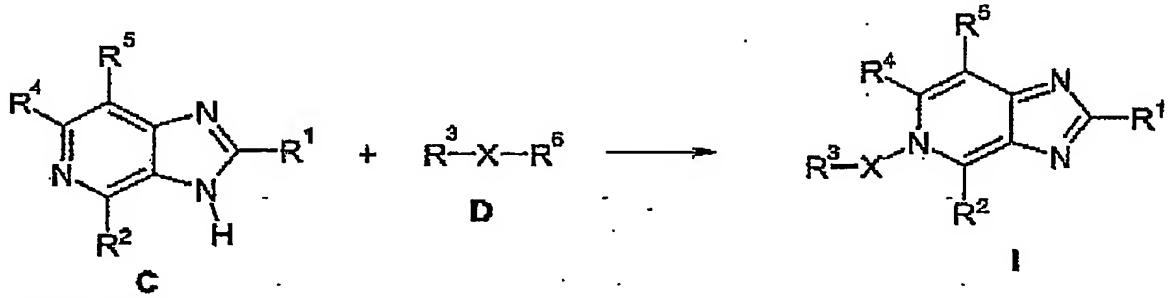
Scheme 2:



1*H*-C 3*H*-C 5*H*-C

Substituents (R^2, R^4 and/or $R^5 \neq H$) can be introduced by two ways: i) either by cylization of an appropiately substituted 3,4-diaminopyridine A or ii) by introduction of the substituent(s) onto the imidazo[4,5-c]pyridine C. For example, halogens can be introduced in position 7 of the imidazo[4,5-c]pyridine C by direct halogenation (R^5 = Br: with bromine in acetic acid or with NBS in acetic acid; R^5 = Cl: with chlorine in acetic acid or with NCS in acetic acid). Another example is the direct nitration ($R^5 = NO_2$), followed by reduction to give the amino group ($R^5 = NH_2$). Substituents in position 4 of the imidazo[4,5-c]pyridine C can be introduced, for example, *via* the corresponding imidazo[4,5-c]pyridine N^5-oxides.

The second and final step is the reaction of the imidazo[4,5-c]pyridines C with an alkylating agent D (R^6 = Cl, Br, etc.) in an appropiate solvent (preferably DMF) under addition of a base (preferably aqueous sodium hydroxide) at ambient temperature (scheme 3).



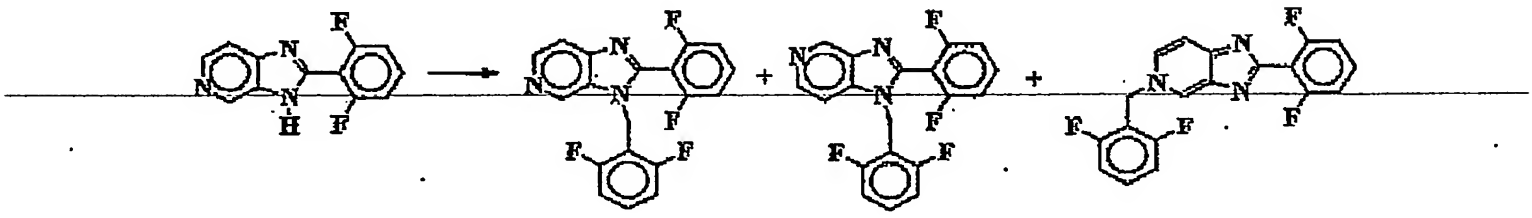
C D I

SCHEME 3:

This reaction gives mixtures of three products (alkylation at the N^1, N^3 or N^5 of the imidazo[4,5-c]pyridine C, respectively). For example, reaction of imidazo[4,5-c]pyridine C

(R^1 = 2,6-difluorophenyl, R^2 = R^4 = R^5 = H) with 2,6-difluorobenzyl bromide gave the following mixture (scheme 4):

SCHEME 4:



16 % 14 % GPRTI-8 (65 %)

This mixture can be separated by column chromatography (silica gel, eluent: mixture of dichloromethane and methanol). The structures of the isolated components can then be assigned by NMR spectroscopy (for example by one-dimensional NOE-techniques: irradiation at the CH_2 resonance frequency; applying this to GPRTI-8 gives signal enhancements of the protons in positions 4 and 6 of the imidazo[4,5-c]pyridine ringsystem) or by single crystal x-ray analysis.

Alternatively, the crude reaction mixture can be recrystallized from an appropiate solvent (mixture), e.g. from a mixture of diisopropyl ether and ethyl acetate, to give the pure N^5 alkylated products.

METHODOLOGY FOR DETERMINATION OF ANTIVIRAL AND CYTOSTATIC ACTIVITY

Antiviral and cytostatic activity are determined by the Methodology described below:

Cells and viruses: Madin-Darbey Bovine Kidney (MDBK) cells were maintained in Dulbecco's modified Eagle medium (DMEM) supplemented with BVDV-free 5% fetal calf serum (DMEME-FCS) at 37°C in a humidified, 5% CO_2 atmosphere. BVDV-1 (strain PE515) was used to assess the antiviral activity in MDBK cells. Vero cells were maintained in the same way as MDBK cells. Vero cells were infected with Coxsackie B3 virus (strain Nancy).

Anti-BVDV assay: Ninety-six-well cell culture plates were seeded with MDBK cells in DMEM-FCS so that cells reached 24 hr later confluency. Then medium was removed and serial 5-fold dilutions of the test compounds were added in a total volume of 100 ul, after which the virus inoculum (100 ul) was added to each well. The virus inoculum used resulted in a greater than 90% destruction of the cell monolayer after 5 days incubation at 37°C. Uninfected cells and cells receiving virus without compound were included in each asay plate. After 5 days, medium was removed and 90 µl of DMEM-FCS and 10 ul of MTS/PMS solution (Promega) was added to each well. Following a 2 hr incubation period at 37°C the optical density of the wells was read at 498 nm in a microplate reader. The 50% effective concentration (EC_{50}) value was defined as the concentration of compound that protects 50% of the cell monolayer from virus-induced cytopathic effect.
